Sourceline — Production Smoke Test

15 October 2026 · live production, over HTTPS, in Chrome 154 · all flows, all roles

Verdict

105 of 110 checks passed. 3 warnings. 2 failure, found and fixed.

The complete procurement cycle runs in production. A requisition was raised, approved, competitively quoted by three suppliers, awarded, turned into a purchase order worth USD 7,130, taken through all four approval stages including the COO, received into stores, invoiced, three-way matched and paid — then the supplier was evaluated. All fifty steps passed.

All eight roles sign in and every screen each one offers opens. Business units cannot see each other's data. One genuine defect was found: it is fixed and verified, and is described below.

What stops a rollout is not the software. Fourteen of the fifteen units are still empty, the administrator accounts cannot receive email, and two-factor sign-in is switched off.

The defect found, and fixed

A department head outside Procurement could not load their dashboard. `GET /api/dashboard/stats?range=month` returned HTTP 500 in production — likewise week and year. Without the date range it worked, and every other role worked with it, which is how it survived.

Cause. The sign-in middleware loads the user's department as a full record. The dashboard passed that record where an identifier was expected, and the database driver rejected it. Only the non-procurement department head reaches that code path — a Procurement head is treated as a procurement officer, and no other role filters its charts by department.

Fixed and verified. The role that returned 500 now returns 200 for all three ranges and renders its three charts — Requisition status, Department spend trend, Items requested over time — which it had never been able to show. The four other places that build identifiers the same way were hardened to drop an unusable filter rather than fail the request.

This fix is committed but not yet deployed. Until the next deploy, department heads outside Procurement still see a broken dashboard in production.

The procurement cycle, in production

Run against Dokuma on the live system, not a staging copy. Fifty steps, no failures.

Stage	What ran
Supplier onboarding	Self-registration, procurement activation, KYS and spend authorisation, profile completion
Requisition	Raised as a draft by the end user, submitted, approved by the ICT head, stock-checked by stores, accepted by procurement
Competitive quoting	RFQ published to three suppliers, three quotations received, RFQ closed
Award	Winning quotation selected by the department head, authorised and accepted by procurement
Purchase order	Raised at USD 7,130, then ICT head → Procurement head → Finance → COO, all four required
Receipt	Supplier acknowledged, stores raised a goods received note, stock accepted into inventory
Invoice and payment	Supplier invoiced, three-way match passed, finance approved and paid
After the cycle	Supplier evaluated at 4 of 5, budgets updated, audit log written, notifications delivered

The controls were exercised, not just the happy path: a supplier without KYS cannot be awarded, an invoice for goods never received is refused, and the COO stage is only required above USD 5,000.

Every role, every screen

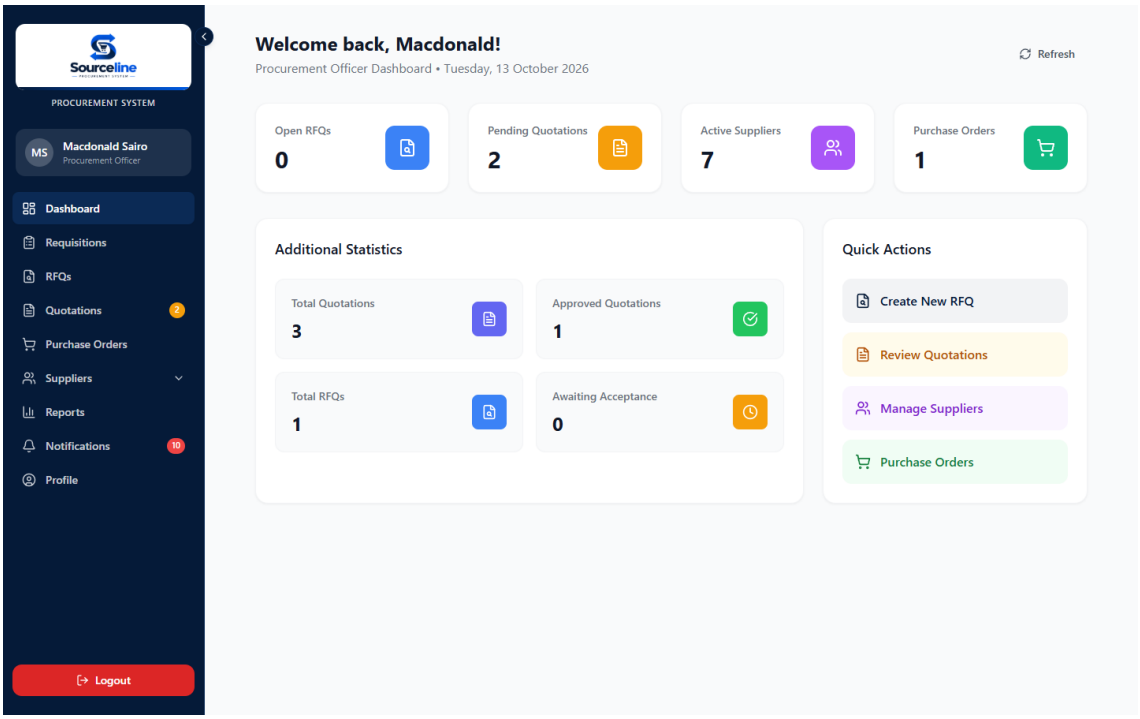

Each role signed in and every item in its own navigation was opened. 69 screens in total; all rendered without an API error apart from the dashboard defect above.

Role	Screens	Covers
System administrator	11	Staff, departments, sites, RFQs, quotations, orders, reports, audit log
Procurement officer	9	Requisitions, RFQs, quotations, purchase orders, reports
Department head (ICT)	8	Approvals, requisitions, store requisitions, reports
Department head (Procurement)	10	Approvals plus the full procurement set
Finance	10	Approvals, invoices, payments, budgets, purchase orders
COO	6	Approvals and reports
Stores officer	11	Stores review, GRVs, inventory, stock movements and transfers
End user	5	Own requisitions and notifications

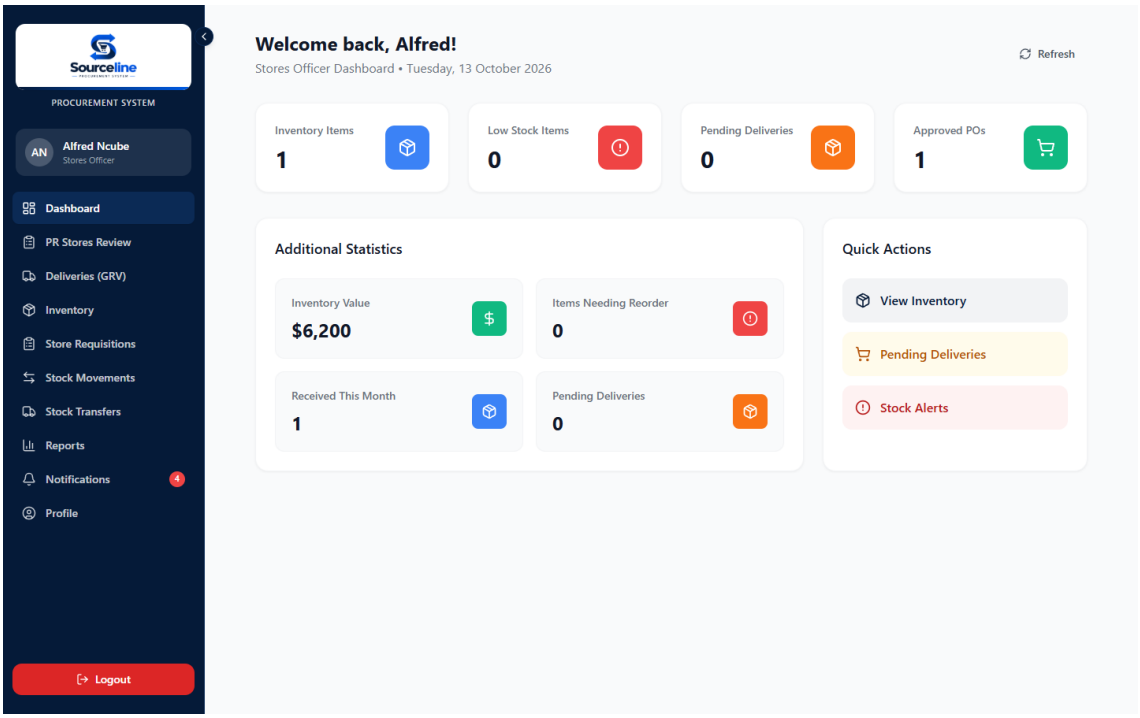

What it looks like

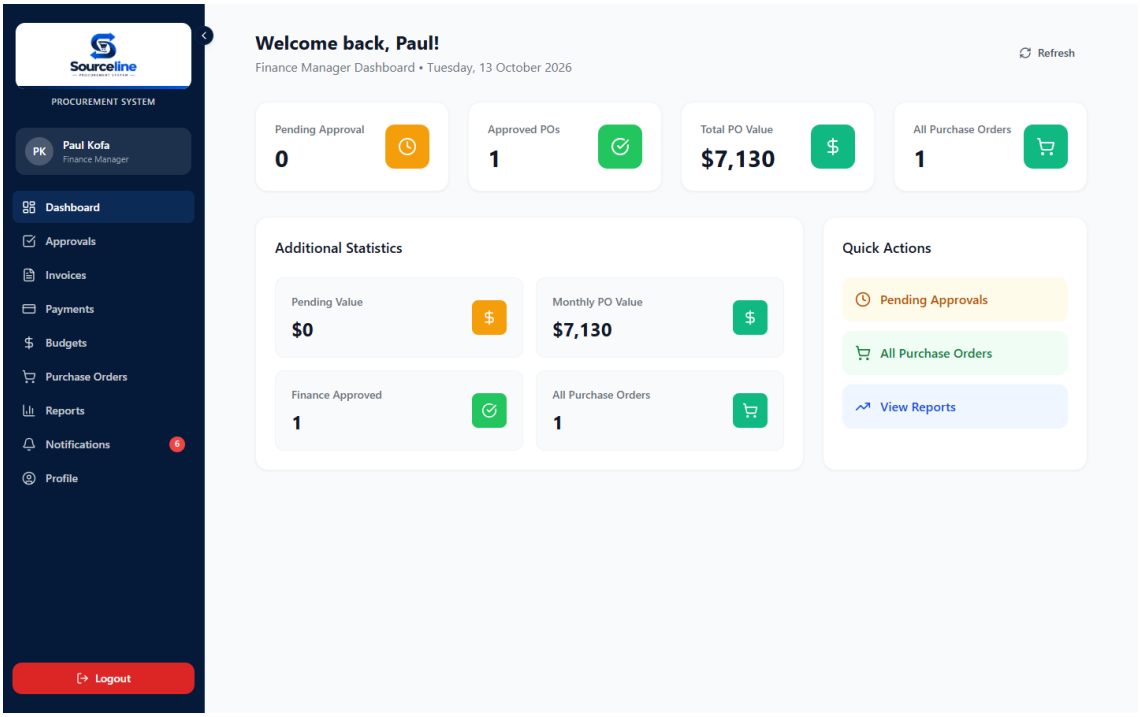

fossil.sourceline.co.zw — the login page, HTTPS with a valid certificate. No business-unit chooser: the address already identified the unit.

Procurement officer, signed in to Dokuma after the cycle ran.

Stores officer — a different role, a different navigation: stores review, goods received notes, inventory, stock movements and transfers.

Finance — approvals, invoices, payments and budgets.

Separation between business units

A session opened against Dokuma was presented to Titan and refused — *"This session belongs to a different business unit. Please sign in again."* (HTTP 401) — while the same session worked normally on Dokuma. An unrecognised origin received no CORS headers at all. Each unit has its own database, and purchase order numbering restarts in each, so two units may both hold PO-2026-00001. That is correct, not a collision.

Warnings

- **group.sourceline.co.zw** and **suppliers.sourceline.co.zw** do not respond. Group reporting and the shared supplier portal are not built, and neither has a certificate. Expected.
- **www.sourceline.co.zw** returns 404 — it points at the application, which has no page there. Redirect it to a business unit or leave it.
- **Dashboards take six to seven seconds** on a cold start for every role. They do load, but slowly enough that a user may think the page has hung.

What needs to be done

Before anyone uses it

1. **Deploy.** The dashboard fix is committed and not yet live. Department heads outside Procurement still get a 500 until it ships.
2. **Fill the other fourteen units.** Dokuma now has staff and suppliers because this test seeded it. The rest hold one administrator and nothing else.
3. **Real email addresses for the administrators.** Theirs end in .sourceline.local, which no mail server can deliver to — no resets, no approvals, no supplier invitations.
4. **Turn two-factor back on** once those work. The verification code is currently handed to the browser, so an email address is enough to sign in as anyone.
5. **Clear the test data from Dokuma** when you are done with it: `npm run migrate:sbu-reset -- --sbu DOKUMA`. It currently holds a real purchase order, invoice and payment that this test created.

Before real money moves through it

1. **Confirm the database tier and backups.** The 500-collection ceiling identifies a shared Atlas tier, which has no automated backup. This is the largest risk currently carried and the only one where waiting cannot be undone.
2. **Move development and staging to their own cluster.** 471 of 500 collections are used; production alone is about 334 of them permanently. At the ceiling, writes fail everywhere — production included.
3. **Update CLIENT_URL on the API.** It is 94 days old and predates these domains, so every link in every email points somewhere wrong.

Known gaps — ship with them, but say so

Gap	Why
Documents print "Fossil Contracting" whichever unit issued them	Per-unit branding not built
Purchase order numbers repeat across units	Per-unit prefix planned, not built
No currency on orders, invoices or payments	Only quotations carry one
The USD 5,000 approval threshold is the same everywhere	Per-unit thresholds not built
A supplier must be onboarded separately in each unit	By design — units share no data
Emails link to one fixed address, not the unit you are in	Per-unit email links not built

Recommendation

Deploy the dashboard fix, then take Dokuma the rest of the way: real staff, real suppliers, working email addresses, two-factor back on, and one genuine procurement cycle run by the people who will actually use it. Apply what that teaches to the other fourteen. Answer the backup question first.

Method: Chrome 154 driven headless against the live production deployment, plus the fifty-step procurement suite run over the production API. Every status code and screenshot here is from those runs. Two sign-in failures in an early pass were a fault in the test harness — it clicked before the form had committed its state — and did not reproduce once corrected.
